Among them, luminescence is one of the important investigation aspects, which is relevant to the unique structural, carrier transport, photonic, and optoelectronic properties of 2D materials. Herein, a general overview of recent advances of luminescence in 2D systems, including 2D materials and van der Waals heterostructures, is given.

Although the 2D materials are interesting in their own right, an even larger potential lies in the possibility of reassembling different 2D crystals into new layered compounds . Such designer materials have been coined van der Waals heterostructures (vdWHs) with reference to the weak van der Waals forces holding the 2D crystal planes together.

In commonly used 2D materials, researchers rely on the interaction between the thin layers, known as van der Waals interlayer coupling, to create charge transfer that is then used in devices. However, this interlayer coupling is limited because the charges are traditionally distributed evenly on the two sides of each layer.
